Proposing an action at mvxsafe.io

A one-page guide for whoever asks a safe to move funds

Nothing leaves a safe until **enough board members have signed**. Proposing puts a request in front of them. On its own it **moves nothing**.

You need a wallet that sits on the safe's board or is one of its proposers. You also need a little EGLD for fees: around 0.05 is plenty.

1 Open the safe and connect your wallet

Go to **mvxsafe.io**, open the safe and press **Connect**.

- Choose how you sign: **xPortal** (scan the code with your phone), the MultiversX **browser extension**, a **Ledger**, the **web wallet** or **MetaMask** on a computer.
- If the safe is not in your list yet, paste its address under **Add a safe**.

2 Fill in the proposal

Under **Propose an action**, choose **Send tokens**. For EGLD, the network coin, choose **Send EGLD**.

- **Token:** check its full code, not only its name. A token with another code is another token.
- **Recipient:** paste the address and check it twice, character by character, against where it came from.
- **Amount:** start with a small test amount when the address is new to you. Send the rest once the test has arrived.

Press **Propose** and confirm in your wallet. A board member who proposes has signed by doing so. A proposer has not, as proposers never sign.

3 Tell the others

Tell the board members who still have to sign what you proposed, by phone or message: the token, the amount and the whole address. They read it on their own screen and sign. The signer's guide shows them how.

4 Carry it out

Once the signatures reach the quorum, a **Carry it out** button appears. Pressing it is what actually moves the funds: **nothing moves before it**.

- Any board member or proposer can press it. Leave the gas figure as it is.
- The action then joins the safe's history, linked to the explorer. Check that it arrived before you send more.

> **Changed your mind?** While the action waits, **Remove my signature** takes your approval back. Once no signature is left on it, **Discard** throws it away. Changes to the board, the quorum and contract calls follow the same steps: the full guide at mvxsafe.io/guide covers them.

mvxsafe.io is open source: github.com/foxsyai/mvxsafe. It never holds keys. Any copy of it shows the same safe, as does any other interface for the same contract.
